Taking Care of Your Septic Tank System

An Ounce Of Prevention Is Worth A Ton Of Cure!

Committing a little attention to the care of your system can avoid the nightmare of a failing system. Assuming that your septic tank system was properly located, designed, and installed according to state codes, you are now in the driver’s seat for the care of your system. By following the recommendations below, you can help your system to work properly for years to come.

Do’s

- Conserve water to reduce the amount of wastewater that must be treated and disposed of by your system. Doing laundry over several days will put less stress on your system.
- Repair any leaking faucets or toilets. To detect toilet leaks, add several drops of food dye to the toilet tank and see if dye ends up in the bowl.
- Divert roof drainage, down spouts and other surface water away from your drain field. Excessive water keeps the soil from adequately cleansing the wastewater.
- Install an effluent filter in your tank the next time it is pumped.
- Have your septic tank inspected yearly and pumped regularly by a licensed septic tank contractor.* See the chart below for suggested pumping frequencies.
- Keep your septic tank cover accessible for inspections and pumpings by installing watertight steel rod into the soil about 5-10 feet away from the house to the access port on the tank. You may want to have a watertight access riser and secure lid extended up to ground level. This will help you find it again and may reduce your pumping fee.
- If the house sewer pipe enters the soil, then, gently push a thin (3/8 to 1/2 inch diameter) steel rod into the soil about 5-10 feet away from the house to the access port on the tank. You may want to have a watertight access riser and secure lid extended up to ground level. This will help you find it again and may reduce your pumping fee.
- Keep your permit in this file folder for future reference and to pass on to the next homeowners.
- Make a sketch on the grid provided below locating your septic tank and drain field (the trenches) in relation to surrounding reference points. Begin by sketching your house, driveway, water well, and other landscape features, such as trees or fences.
- A good starting point for finding the exact location of the tank is to look in the crawl space to see the direction in which the house sewer pipe enters the soil. Then, gently push a thin (3/8 to 1/2 inch diameter) steel rod into the soil about 5-10 feet away from the house to feel for the tank. Of course, you should first call local utility companies to make sure there are not any underground utilities (such as buried electrical cables) in the area.
- When you have your septic tank pumped, measure and record the distance from the house to the access port on the tank. You may want to have a watertight access riser and secure lid extended up to ground level. This will help you find it again and may reduce your pumping fee.

Don’ts

- Don’t drive over your drain field or compact the soil in any way.
- Don’t dig in your drain field or build anything over it, and don’t cover it with a hard surface such as concrete or asphalt and don’t install underground utilities or sprinkler systems nearby.
- Don’t plant anything over or near the drain field except grass. Roots from nearby trees and shrubs may clog and damage the drain lines.
- Don’t install a swimming pool near your system.
- Don’t use a garbage disposal, or at least limit its usage. Disposals increase solids in your tank by about 50%, so you have to pump your tank more often than normally suggested.
- Don’t use your toilet as a trash can or poison your system and the groundwater by pouring harmful chemicals and cleansers down the drain. Harm chemicals can kill the bacteria that help purify your wastewater. See the list below for examples.
- Don’t waste money on septic tank additives. The bacteria needed to treat wastewater are naturally present in sewage. Additives can re-suspend solids causing your drain field to clog. Additives do not eliminate the need for routine pumping of your tank.
- Don’t allow backwash from home water softeners to enter the septic tank system.
- Never enter a septic tank. Toxic gases from the tank can kill. If your system develops problems, get advice from your county health department or a licensed septic tank contractor.

Septic System Location?

When you have your septic tank pumped, you may reduce your pumping fee.

Suggested Pumping Frequency (Years)

Did you know….

… that a properly designed and installed septic tank system can be the safest, most economical way to treat your wastewater as long as it is properly maintained? If you are like most homeowners, you probably never give much thought to what goes down your drain. But if you own a car and understand how important it is to do preventative maintenance (like changing your oil), then you can understand how maintaining your septic tank system can save you money and headaches down the road. This owner’s guide can help you be sure that your septic tank system is used and maintained properly. This folder also provides a place to record and keep important information such as your permit, a sketch of your system, maintenance records, and other fact sheets. Read and use this folder to learn:

- How a septic tank system works
- Why and how to maintain your septic tank system
- How to keep your own maintenance record

System Description. A septic tank system uses natural processes to treat and dispose of the wastewater generated in your home. It typically consists of a septic tank with an effluent filter and a drain field, or a soil absorption field. The septic tank provides the first step in treatment. As wastewater flows into the tank, the heavier solids settle to the bottom to form a sludge layer, and the lighter solids, greases, and oils float to the top to form a scum layer. The liquid wastewater (effluent) from the filtered tank flows into gravel-filled trenches in the drain field where it spreads out via perforated pipes, and is treated by the natural soil system. The diagram below shows the components of a typical septic tank system.

System Operation. The septic tank provides some biological treatment of the sludge and scum layers that accumulate there. The majority of treatment occurs in the drain field where the effluent enters the soil and is treated as it percolates to the groundwater. The soil acts as a biological and physical filter to remove harmful substances including disease-causing bacteria and viruses, toxic organics and other undesirable wastewater constituents remaining in the effluent.

A baffle and filtered outlet tee located in the tank are designed to prevent the sludge and scum from flowing into the drain field. If the tank is not pumped regularly to remove the accumulated solids, the tank will fill with sludge and the solids will be washed out into the drain field. There they will quickly clog the soil and eventually cause the system to fail.

Maintenance Record

Use the Following Spaces to record information about your own septic tank system. Some of this can be copied from your Approval for Use, which can be obtained from your county health department. Having good maintenance records can be a positive selling point for your home when the time comes (wouldn’t you rather buy a car that has a proven maintenance record?)
